ZOO 301 Current Final Term Spring 2021

MCQ

1. Which hormone cause the pancreases to release digestive enzymes? **Gastrin**

2. Inhibitory and releasing hormones are produced by the_____. **Hypothalamus**

3. _____ is a hormone produced by the Thyroid gland. **Calcitonin**

4. Which hormone maintain pregnancy? **Progesterone**

5. Which hormone target the skeletal muscle cells? **Insulin**

6. The cavity between thin layers of epithelium and parietal pleura is_____? **Pleural cavity**

7. Which one of the following is function of Erythropoietin? **Stimulate RBC production**

8. Thyroid stimulating hormone is produced by _____. **Thyroid gland**

9. What links the body and the brain? **Spinal cord**

10. Which part of bony fishes is richly supplied with blood to facilitate in respiration? **Dermis**

11. Lymphatic system present in all except,

A. Spleen **B. Red bone marrow** C. Thymus D. Lymphoid node

12. Which invertebrate do not have well developed excretory and respiratory system? **Cnidarians (Hydra)**

13. Ear of snake lake _____and tympanum (Ear drum). **Middle ear cavity**

14.Which is neuroendocrine gland in adrenal medulla? **Chromaffin**

15.Adrenal gland are present on? **Upper part of kidney**

16.Temperature of egg is maintained between? **33-37**

17. Killer T cells are found in_____? **Cancerous cells**

EFFORT BY AMAAN KHAN

VU Medical Zone Effort By Amaan Khan

18. _____influences certain aspects of epidermal development such as tanning (i.e. hardening, and darkening of chitinious outer cuticle layer). **Buriscon**

19. What is evolutionary transition between aquatic and terrestrial animal? **Bimodal Breathing**

20. Adult fishes have gills covered with_____. **Operculum**

21. Oxyhemoglobin concentration depends upon_____. **Altitude**

22.Innate immune system is exhibited by_____. **Natural killer cells**

23. In birds, mammals and crocodile, the ventricle is divided, forming_____. **Four chambered heart**

24. _____are respiratory organ having thin moist epidermis over highly vascularized dermis for gaseous exchange. **Gills**

25. Fluid-filled internal gastro cavity is present in? **Cnidarians or Hydra**

26. How many veins are emerged from kidney after division and open into post caval vein? **5-6**

27. 1st line of defense_____. **Skin and Mucous membrane**

28. Function of prolactin_____. **Milk production or burrowing**

29. Alpha cells produce_____. **Glucagon**

30.Protozoa breathe by_____ **Simple diffusion**

31. Oxytocin produce in_____. **Hypothalamus**

32. How many hormones are produced by kidney? **Three**

33. The organ that produce sperm and male hormone_____. **Testosterone**

34. ECG recorded by device called_____. **Electrocardiograph**

35.What are primary colors? **Yellow, red and blue**

36.Third eye is also known_____. **Pineal gland**

37. How much CO concentration can cause death? **1%**

VU Medical Zone Effort By Amaan Khan

38. Bombykol is a_____? **Pheromone**

39. Condition relate to low calcium is_____. **Hypocalcemia or Tetany**

40. Amphibian's lungs are_____. **Sac-like**

41. How many hormones are produced by pituitary gland? **Nine**

42. Accumulation of lactic acid cause_____. **Muscle fatigue**

43. What is mass of Hemoglobin in RBC? **95%**

44. The amount of waste in RBC_____. **5%**

45. How many chambers Boney fish has? **Two**

46. How many % does Amphibian receive oxygen by cutaneous respiration? **25%**

47. Pearls are formed in_____. **Mulluscan bivalves**

48. Which is sound is not hearable by human ear? **Less than 20 cycle per sec**

49. Outer layer of adrenal gland is called_____. **Cortex**

50. Connective tissues surrounding muscle fiber are? **Endomycium**

51. Blood is known as_____. **Soft connective tissue**

52._____ is example of passive immunity. **Mother milk**

53. Which is the second largest part of brain? **Cerebellum**

54. Pituitary gland is also called as_____. **Hypophysis**

55. Chlorocruorin contain iron but is_____ when associated with low oxygen and_____ when associated with high oxygen. **Green and bright red**

56. When diaphragm contracts and flattens the thoracic cavity? **Enlarge**

57. Atrial systole and ventricular diastole last for_____. **0.1 sec**

58. Atrial diastole and ventricular systole last for_____. **0.3 sec**

59. Testes are also called_____. **Testicles**

VU Medical Zone Effort By Amaan Khan

60. Semicircular canals in inner ear are used for orientation determination and_____. **Regulate balance**

61. Too much production of thyroid causes_____. **Hyperthyroidism**

62. In teleosts, the chromaffin tissue is generally present at_____ of kidney? **Anterior end** 63. Neurosecretory cells of arthropods brains produce hormone_____. **Buriscon Hormone**

64. Exchange of respiratory gases through three surfaces_____. **Trimodal Breathing**

65. How many mechanisms of hormone action are? **2**

Q1. What are Gills? 3 Marks

Gills are respiratory organs that have thin, moist epidermis over highly vascularized dermis for gaseous exchange. Larval forms of a few fishes and amphibians have external gills projecting from their bodies. Adult fishes have internal gills covered with operculum.

Q2. What is the function of progesterone in Female? 3 Marks

The progestins (primarily progesterone) also regulate the menstrual and estrus cycles, and the development of mammary glands. It also aids in placenta formation during pregnancy.

Q3. Feedback System. 2 Marks

Hormones are not released in a constant, steady stream. Rather they are secreted in fluctuations depending on the physiological demand for their actions.

Q4. What type of circulatory system are involved in Annelids? 2 Marks

The annelids, such as the earthworm, have a closed circulatory system in which blood travels through vessels delivering nutrients to cells and removing wastes.

VU Medical Zone Effort By Amaan Khan

Q5. Write a note on Granulocytes RBCs? 5 Marks

Granulocytes have granules in their cytoplasm and they include:

• Neutrophils

• Eosinophils

• Basophils

Eosinophils are phagocytic, and ingest foreign proteins and immune complexes rather than bacteria. In mammals, eosinophils also release chemicals that counteract the effects of certain inflammatory chemicals released during allergic reactions.

Basophils are the least numerous WBC. When they react with a foreign substance, their granules release histamine and heparin. Histamine causes blood vessels to dilate and leak fluid at a site of inflammation, and heparin prevents blood clotting.

Neutrophils are the most numerous of the white blood cells. They are chemically attracted to sites of inflammation and are active phagocytes.

Q6. Write the Characteristics of Hormones? 5 Marks

General characteristics of hormones are as follows:

i) Hormones are secreted by specialized cells, the endocrine cells.

ii) Hormones are chemical messengers. They are chemical signals that circulate in the body fluids.

iii) Hormones are directly secreted into the blood stream and are carried by the blood throughout the entire body, yet they affect only certain cells.

iv) Specific cells that respond to a given hormone have receptor sites for that hormone.

v) Hormones are required in very minute quantities.

VU Medical Zone Effort By Amaan Khan

Q7. What is neurosecretory cell? 3 Marks

Neuropeptides. Some specialized neurons (called neurosecretory cells) secrete neuropeptides (neurohormones). The blood or other body fluids transport neuropeptides to nonadjacent target cells, where neuropeptides exert their effects.

Q8. What type of respiratory system have Molluscs? 2 Marks

Molluscs have gills that are compact and protected with hard covering devices. Such gills divide into highly branched structures to maximize the area for gas exchange.

Q9. Function of Prolactin in pigeon? 2 Marks

Prolactin stimulates the production of "pigeon's milk" by desquamation (sloughing off cells) in the pigeon's crop. Prolactin also stimulates the development of the brood (incubation) patch.

Q10. Types of Lymphocytes? 3 Marks

Lymphocytes are of types of two types: B cells and T cells, both of which are central to the immune response.

B cells originate in the bone marrow and colonize the lymphoid tissue, where they mature.

T cells are associated with and influenced by the thymus gland before they colonize lymphoid tissue and play their role in the immune response.

Q11. External Respiration? 2 Marks

Animals that respire aerobically need a constant supply of oxygen. The process of acquiring oxygen and eliminating carbon dioxide is called external respiration.

VU Medical Zone Effort By Amaan Khan

Q12. What is Hormone? 2 Marks

Endocrine glands or cells secrete hormones that the bloodstream transports to nonadjacent target cells is called Hormones. For example, Thyroxin, Insulin, Glucagon, FSH and LH etc.

Q13. Renal Portal System? 3 Marks

Renal Portal System

The veins which carry blood to capillary system in kidneys constitute the renal portal system. The renal portal vein collects blood from all parts of the hind limbs and enters the kidney by number of branches from outer margin. Inside the kidney these veins divide and redivide to form capillaries. These capillaries form 5 to 6 renal veins on emerging from the kidneys and open into post caval vein. All these veins form renal portal system.

Q14. Biochemical Nature of Hormone? 5 Marks

Biochemically the hormones may be the

i) Proteins (polypeptides) e.g. insulin

ii) Derivatives of amino acids (amines), e.g. TSH

iii) Steroids e.g. Sex hormones and adrenocortical hormones.

iv) A few are fatty acid derivatives. For example- Postglndins. They are synthesized in the walls of blood vessels. Regulate the contraction of smooth muscle tissue. Involved in inflammation.

VU Medical Zone Effort By Amaan Khan

Q15. Function of Prolactin in Fishes? 2 Marks

Prolactin causes brooding behavior in some fishes. It is also essential for certain saltwater fishes to enter freshwater during spawning.

Q16. 1st Line of Defense? 3 Marks

Rapid cell division occurs in the deeper parts of epidermis. As these cells come up the surface they die and become keratinized. Later these cells become the outer skin layer, and called the stratum corneum. As these cells come on the surface and die and become keratinized. Later these cells become the outer skin layer, and called the stratum corneum. The SC is the first line of defense against toxins and microbes.

Q17. Role of Bursicon? 2 Marks

Bursicon influences certain aspects of epidermal development, such as tanning (i.e., hardening and darkening of the chitinous outer cuticle layer).

Q18. Role of lymphocytes? 3 Marks

Lymphocyte is a type of white blood cell (leukocyte) that is of fundamental importance in the immune system. Lymphocytes are the cells that determine the specificity of the immune response to pathogens and other foreign substances.

Q19. Cuticle formation in Arthropods? 5 Marks

The sequence of events in insects is similar to that of crustaceans, but it does not involve a molt inhibiting hormone. The presence of an appropriate stimulus to the central nervous system activates certain neurosecretory cells (pars intercerebralis) in the optic lobes of the brain. These cells secrete the hormone ecdysiotropin, which axons transport to the corpora cardiaca (a mass of neurons associated with the brain). The Corpora Cardiaca produces thoracotropic hormone, which is carried to the prothoracic glands, stimulating them to produce and release ecdysone, which induces molting, the reabsorption of some of the old cuticle and the development of a new cuticle.

Q20. Write a note on Bimodal breathing? 5 Marks

EFFORT BY AMAAN KHAN

VU Medical Zone Effort By Amaan Khan

Bimodal breathing is the ability of an organism to exchange respiratory gases simultaneously with both air and water. e.g., some salamanders, crabs, barnacles, bivalve molluscs, and lung fishes. These animals use gills for water breathing and lungs for air breathing. Bimodal breathing was an important respiratory adaptation with evolutionary transition between aquatic and terrestrial habitats. Fundamental changes in the structure and function of the respiratory organs accompanied the transition from water to air breathing. In terrestrial vertebrates i.e. reptiles, birds, and mammals, gills were replaced with lungs. Cutaneous, gills and lungs are the three vertebrate respiratory surfaces.

Q21. Heart Beat rate in adult? 2 Marks

Adult human heart beats or pumps 72 times a minute.

Q22. Phases of Breathing? 3 Marks

Ventilation or breathing has two phases:

• 1. inhalation, the intake of air; and

• 2. exhalation, the outflow of air.

These air movements result from the rhythmic increases and decreases in thoracic cavity volume. Changes in thoracic volume leads to reversals in the pressure gradients between the lungs and the atmosphere; gases in the respiratory system follow these gradients.

Q23. Role of Thyroxine and triiodothyronine in metamorphosis? 3 Marks

Thyroxine and triiodothyronine control metamorphosis in the frog. Low thyroxine and triiodothyronine concentrations and high prolactin concentrations in young tadpoles stimulate larval growth and prevent metamorphosis.

Q24. Types of Vaccine? 5 Marks

There are 4 main types of vaccines:

VU Medical Zone Effort By Amaan Khan

• Live-attenuated vaccines.

• Inactivated vaccines.

• Subunit, recombinant, polysaccharide, and conjugate vaccines.

• Toxoid vaccines.

Q25. What is chemical messenger? 2 Marks

Chemical messengers are involved in

Communication.

Maintenance of homeostasis in an animal's body.

Body's response to various stimuli.

Q26. Function of nerve cells in Hydra? 2 Marks

The nerve cells of Hydra contain a growth promoting hormone that stimulates budding, regeneration, and growth.

Q27. Vaccine? 3 Marks

Vaccine is a substance used to stimulate the production of antibodies and provide immunity against one or several diseases.

• Vaccines are prepared from the causative agent of a disease or its products.

• It may be a synthetic substitute, treated to act as an antigen without inducing the disease.

• "There is no vaccine against the virus ".

Q28. Write down the mechanism of inhalation in Human? 5 Marks

EFFORT BY AMAAN KHAN

VU Medical Zone Effort By Amaan Khan

• Several sets of muscles, the main ones being the diaphragm and intercostal muscles, contract.

• The intercostal muscles stretch from rib to rib, and when they contract, they pull the ribs closer together, enlarging the thoracic cavity.

• The thoracic cavity further enlarges when the diaphragm contracts and flattens.

• The increased size of the thoracic cavity causes pressure in the cavity to drop below the atmospheric pressure.

• Air rushes into the lungs, and the lungs inflate.

Q29. What is neuropeptide? 2 Marks

Neuropeptides are specialized neurons (called neurosecretory cells) which secrete neuropeptides (neurohormones). The blood or other body fluids transport neuropeptides to nonadjacent target cells, where neuropeptides exert their effects.

Q30. Define Arteries. 2 Marks

Arteries are elastic blood vessels that carry blood away from the heart to the organs and tissues of the body. The central canal of an artery (and of all blood vessels) is a lumen.

Q31. Define veins. 2 Marks

Veins are relatively inelastic and the wall of a vein contains the same three layers (tunicae) as arterial walls, but the middle layer is much thinner. One or more valves are present which permit blood flow only in one direction.

Q32. Define capillaries. 2 Marks

VU Medical Zone Effort By Amaan Khan

Capillaries are generally composed of a single layer of endothelial cells and are the most numerous blood vessels in an animal's body.

Q33. What happen when neuropeptide is injected in sea star? 3 Marks

When this neuropeptide is injected into a mature sea star, it induces immediate shedding of the gametes, spawning behavior, and meiosis in the oocytes. The neuropeptide also causes the release of a hormone called maturation-inducing substance, which has various effects on the reproductive system.

Q34. What is air conducting portion in human? 2 Marks

Air Conducting portion are the air passage ways that consist of nostrils, nasal cavities, pharynx, larynx, trachea, bronchi, bronchioles and alveolar ducts which ultimately leads into the alveolar sacs.

Q35. Fixed membrane-receptor mechanism of hormones? 5 Marks

This complex activates the enzyme-adenylate cyclase in the membrane.

The activated enzyme converts ATP into a nucleotide called cyclic AMP.

Cyclic AMP diffuses throughout the cytoplasm and activates an enzyme called protein kinase.

Which then phosphorylates specific proteins in the cell, thereby triggering the biochemical reaction, leading ultimately to the cell's response.

After inducing the target cell to perform its specific function, the phosphodiesterase inactivates cyclic AMP

In the meantime, the receptor on the plasma membrane loses the first messenger and now becomes available for a new reaction.

Q36. Working of air conduction in human? 5 Marks

VU Medical Zone Effort By Amaan Khan

Air Conducting portion are the air passage ways that consist of nostrils, nasal cavities, pharynx, larynx, trachea, bronchi, bronchioles and alveolar ducts which ultimately leads into the alveolar sacs.

As air enters through nostrils up to alveoli, air is filtered, moistened and conditioned.

In the pharynx the traffic of air and food is kept properly channeled by flap called epiglottis.

Alveoli are single layered endothelial walls.

Overlying the alveoli there is rich network of blood capillaries providing site for gaseous exchange.

The air passage ways are kept from collapsing by cartilage C-shaped rings in trachea and complete rings in bronchi.

The rings are progressively replaced by irregular cartilage plates.

The bronchioles totally lack cartilage but made of mainly circular smooth muscles.

Q37. What is Feedback system? 2 Marks

Feedback system can be defined as the system in which the controlling mechanism is itself controlled by the product of the reaction it is controlling. e.g. incubator, toaster, iron.

Q38. What is Second line of defense? 2 Marks

Second line of defense is internal. It includes

1. Phagocytic WBCs
2. Antimicrobial proteins
3. Inflammatory response

Q39. Write a note on single circuit circulation? 5 marks

The bony fish heart has two chambers the atrium and ventricle.

VU Medical Zone Effort By Amaan Khan

• Blood leaves the heart via the ventral aorta, which goes to the gills.

• In the gills, blood becomes oxygenated, loses carbon dioxide, and enters the dorsal aorta.

• The dorsal aorta distributes blood to all of the body organs, and then blood returns to the heart via the venous system.

• Because blood only passes through the heart once, this system is called a single circulation circuit.

• The blood pumped out to the rest of the body is thus highly oxygenated.

• In the heart of most reptiles, the ventricle is partially divided into a right and left side.

• Oxygenated blood from the lungs returns to the left side of the heart via the pulmonary vein and does not mix much with deoxygenated blood in the right side of the heart.

• When the ventricles contract, blood is pumped out two aortae for distribution throughout the body, as well as to the lungs.

• The incomplete separation of the ventricles is an important adaptation for reptiles, such as turtles.

VU Medical Zone Effort By Amaan Khan

Q40. What are the chromaffin tissues? 3 Marks

Chromaffin tissue is a group of neuroendocrine cells in the adrenal medulla that synthesizes steroid hormones. These hormones are adrenaline (epinephrine) and noradrenaline (norepinephrine) These hormones prepare some vertebrates for stressful emergency situations (fight and flight).

Q41. What is pleural cavity? 3 Marks

Lungs are covered by a thin layer of tough epithelium called visceral pleura. A similar layer, parietal pleura lines the inner surface of the wall of the chest. The cavity between these layers is called pleural cavity.

Q42. Difference between Hepatic and Renal Portal System? 3 Marks

Hepatic Portal System

Nutrients from the small intestine and the right half of the colon are absorbed into blood through the bed of capillaries.

• This blood then moves to the liver through the Hepatic Portal Vein to store and metabolize in liver.

Renal Portal System

The veins which carry blood to capillary system in kidneys constitute the renal portal system.

• The renal portal vein collects blood from all parts of the hind limbs and enters the kidney by number of branches from outer margin.

Q43. Explain the functions of Thymus? 3 Marks

Thymus

The thymus gland is a small organ behind the breastbone (sternum) that plays an important function both in the immune system and endocrine system.

Functions:

• Thymus produces, the hormone thymosin.

• It stimulates the development of white blood cells, called T-lymphocytes, which protect the body against infections.

•T-cells created by the thymus also help other organs in the immune system grow properly.

Q44. Vertebrate Blood Vessels? 5 Marks

• The blood vessels are the components of the circulatory system that transports blood throughout the vertebrate body

• As blood leaves the heart it travels from arteries to arterioles to capillaries to venules to veins which return it finally to the heart.

VU Medical Zone Effort By Amaan Khan

Arteries are elastic blood vessels that carry blood away from the heart to the organs and tissues of the body.

• The central canal of an artery (and of all blood vessels) is a lumen.

• Surrounding the lumen of an artery is a thick wall composed of three layers.

Veins are relatively inelastic

• The wall of a vein contains the same three layers (tunicae) as arterial walls, but the middle layer is much thinner.

• One or more valves are present which permit blood flow only in one direction.

Capillaries are generally composed of a single layer of endothelial cells and are the most numerous blood vessels in an animal's body

• An abundance of capillaries makes an enormous surface area available for the exchange of gases, fluids, nutrients, and wastes between the blood and nearby cells.

VU Medical Zone Effort By Amaan Khan

Q45. Feedback mechanisms? 2 Marks

The endocrine system is controlled by complex feedback mechanisms in which the secretion of a hormone is turned on (stimulated) or turned off (inhibited), depending on its concentration.

Q46. Cutaneous Respiration? 3 Marks

It is the exchange of gases through skin. Cutaneous exchange is most highly developed in frogs, toads, lung less salamanders and newts. Some more vertebrates such as some aquatic turtles, salamanders with lungs, snakes, fishes, and mammals (Bat).

Q47. Write a note on Vertebrate lymphatic Systems? 5 Marks

• The system begins with network of lymphatic vessels that carry a clear fluid called lymph. The small lymphatic capillaries merge to form larger lymphatic vessels called lymphatics. Lymphatics are thin-walled vessels with valves that ensure the one-way flow of lymph. Lymph is the extracellular fluid that seeps from the bloodstream and accumulates in the lymph vessels. The lymphatic vessels pass through the lymph nodes on their way back to the heart. Lymph nodes concentrate in several areas of the body and act as disposal centers for foreign particles and cellular debris. They play an important role in the body's defense against disease. The system also helps transport lipids that have been absorbed from the small intestine. In addition to the lymph nodes, the mammalian lymphatic system consists of lymphoid organs—the spleen the thymus gland, tonsils, and adenoids. In birds the bursa of Fabricius is an additional lymphoid tissue. The system also helps transport lipids that have been absorbed from the small intestine. In addition to the previously mentioned parts, the lymphatic system of birds and mammals consists of lymphoid organs—the spleen and or the thymus gland, tonsils, and adenoids in mammals.

VU Medical Zone Effort By Amaan Khan

Q48. Systemic circulatory circuit of blood? 2 Marks

The systemic circuit supplies all the cells, tissues, and organs of the body with oxygen rich blood and returns oxygen-poor blood to the heart.

Q49. What happened if thyroxin and triiodothyronine become low in frog? 2 Marks

Low thyroxin and triiodothyronine concentrations and high prolactin concentrations in young tadpoles stimulate larval growth and prevent metamorphosis.

Q50. How many red blood cells are produced by the bone marrow? 2 Marks

Human marrow produces approximately 500 billion blood cells per day.

Q51. Kidney Hormones? 2 Marks

Kidney Produces three hormones:

1. Erythropoietin

2. Urotensin and

3. Calcitrol

Q52. Compare endocrine and exocrine gland. 3 Marks

Exocrine Glands: These glands secrete chemicals into ducts that, in turn, empty into body cavities or onto body surfaces (e.g., mammary, salivary, and sweat glands).

Endocrine Glands: These glands, have no ducts and secrete chemical messengers, the hormones, directly into the tissue space next to each endocrine cell. The hormones then diffuse into the blood stream, which carries them throughout the body to their target cells.

Q53. Write a note on passive immunity? 5 Marks

Passive immunity is conferred from outside the body, so it doesn't require exposure to an infectious agent or its antigen. There is no delay in the action of passive immunity. Its response to an infectious agent is immediate. Passive immunity is not as long-lasting as active immunity. An example of natural passive immunity is a baby's protection against certain infections by getting antibodies through colostrum or breast milk. An example of artificial passive immunity is getting an injection of antisera, which is a suspension of antibody particles. Artificially-acquired passive immunity is an immediate, but short-term immunization provided by the injection of antibodies, such as gamma globulin, that are not produced by the recipient's cells. These antibodies are developed in another individual or animal and then injected into another individual.

Q54. What is ventilation? 2 Marks

VU Medical Zone Effort By Amaan Khan

The air-conducting portion of the respiratory system of air-breathing vertebrates moves air into (inhalation) and out of (exhalation) this system. This process of air movement is called ventilation.

Q55. Explain the functions of Adrenal hormones? 5 Marks

The adrenal cortex secretes three classes of steroid hormones:

1. Glucocorticoids (cortisol),

2. Mineralocorticoids (aldosterone), and

3. Sex hormones (androgens, estrogens).

The glucocorticoids, such as cortisol, help regulate overall metabolism and the concentration of blood sugar. They also function in defense responses to infection or tissue injury.

Aldosterone helps maintain concentrations of solutes (Na^+) in the extracellular fluid. It plays a major role in maintaining the homeostasis of extracellular fluid.

The sex hormones consist of male hormones called androgens (mainly dehydroepiandrosterone) Lesser amounts of female hormones called estrogens. The adrenal medulla is under neural control.

Q56. What is the role of Chromaffin Tissue? 3 Marks

In jawless and cartilaginous fishes chromaffin tissue develops as clusters near the kidneys. In teleost, the chromaffin tissue is generally at the anterior end of the kidney (pronephric region). In anurans, the chromaffin tissue is interspersed in a diffuse gland on the ventral surface of each kidney. In lizards, the chromaffin tissue forms a capsule around the steroidogenic-producing tissue. In birds, the chromaffin tissue is interspersed within an adrenal capsule.

Q57. What is serum? 2 Marks

Serum is plasma from which fibrinogens have been removed.
