

Discussion question

Researchers generally conclude that the heredity and environment both played an important role in determining intelligence of an individual. Do you think that intelligence is only based on genetic or things in child's environment boost intelligence? Prove your stance with logical reasoning.

one important thing to note about the genetics of intelligence is that it is not controlled by a single "intelligence gene." Instead, it is the result of complex interactions between many genes. Next, it is important to note that genetics and the environment interact to determine exactly how inherited genes are expressed. *For example, if a person has tall parents, it is likely that the individual will also grow to be tall.* However, the exact height the person reaches can be influenced by environmental factors such as nutrition and disease. *A child may be born with genes for brightness, but if that child grows up in a deprived environment where he is malnourished and lacks access to educational opportunities, he may not score well on measures of IQ.*
