human beings produce speech sounds while pushing the air out.

Topic-092: Glottalic Airstream Mechanism

This mechanism involves 'glottis' as the adjective could be used to refer to anything pertaining to the glottis. A glottalic airstream is produced by making a tight closure of the vocal folds and then moving the larynx up or down thus raising of the larynx pushes the air outwards causing an egressive glottalic airstream. Similarly, while lowering, the larynx pulls air into the vocal tract and it is called an ingressive glottalic airstream. Sounds of this type found in human language are called ejective or implosive

Lesson-18

AIRSTREAM MECHANISMS

At the end of this section, the students will be able to:

- EXPLAIN the airstream mechanisms involved in the production of speech sounds as a source of energy.

Topic-090: Airstream Mechanisms

All human speech sounds are produced by making the air move (in oral and nasal cavity) thus creating the airstream. Now the study of how and what type of air move is involved is called the airstream mechanism. Most commonly, the air is moved outwards from the body (creating an egressive airstream) but more rarely, speech sounds are also made by drawing air inward (into the body – an ingressive airstream). In other words, 'airstream' is a term used in phonetics for a physiological process which provides a source of energy capable of being used in speech sound production. There are various forms and mechanisms for initiating the air move. The most common is when the air is moved inwards or outwards by initiating air movement involving 'lungs' (the pulmonic airstream), which is used for producing the majority of human speech sounds. The 'glottalic' airstream mechanism, as its name suggests, uses the movement of the glottis - the aperture between the vocal folds as the source of energy. The third one is the 'velaric' airstream mechanism which involves an airflow produced by a movement of the back of the tongue against the velum.

Topic-091: Pulmonic Airstream Mechanism

Pulmonic airstream mechanism is the most commonly used mechanism for speech production by human beings. Almost all the sounds we produce in speaking are created with the help of air compressed by the lungs. The adjective used for this lung-created airstream is 'pulmonic': the pulmonic airstream may be ingressive (as in breathing in) but for speaking practically, it is always egressive (speech sounds are produced while pushing the air out). In order to understand this mechanism, we'll have to analyze the human respiratory system. Under this system, the respiratory muscles set the air in motion. Lungs – the sponge like tissues – contained within air cage called the diaphragm – contract and enlarge lung cavity thus creating the egressive – ingressive actions. This mechanism set an air flow for speech production and human beings produce speech sounds while pushing the air out.

Topic-092: Glottalic Airstream Mechanism

This mechanism involves 'glottis' as the adjective could be used to refer to anything pertaining to the glottis. A glottalic airstream is produced by making a tight closure of the vocal folds and then moving the larynx up or down thus raising of the larynx pushes the air outwards causing an egressive glottalic airstream. Similarly, while lowering, the larynx pulls air into the vocal tract and it is called an ingressive glottalic airstream. Sounds of this type found in human language are called ejective or implosive

respectively. Glottalization as a process is used for any articulation involving a simultaneous glottal constriction (e.g., a glottal stop). In English, glottal stops are often used in this way to reinforce a voiceless plosive at the end of a word as in *what*. Such sounds, made while the glottis is closed, are produced without the direct involvement of air from the lungs. Air is compressed in the mouth or pharynx

1:01 PM 198 B/S 58

in order to describe 1 of 1

into small constituent units such as "pitch phonemes" and "pitch morphemes". The approach most widely used in Britain takes the tone unit as its basic unit and looks at the different pitch possibilities of the various components of the tone unit (the pre-head, head, tonic syllable/nucleus, tail, etc.). Intonation is said to convey emotions and attitudes. Other linguistic functions have also been claimed (e.g., grammatical structure and new information – the effect of prominence). Interesting relationships exist in English between intonation and grammar; for example, in a few extreme cases a perceived difference in grammatical meaning may depend on the pitch movement.

Topic-087: Explaining Intonation

'Intonation' is pitch variation at sentence level and it could be described in terms of intonational phrase. In order to describe intonation, we need to analyze the role of a 'stressed syllable' (i.e., pitch change of one syllable) which further creates a major change 'tonic accent' (marked with an asterisk) to create the pitch peak in an intonational phrase. Similarly, a formal category of intonational [illegible] is also sometimes recognized (an utterance span dominated by boundary tones). As [illegible] of suprasegmental phonology, [illegible] melody. There are several ways for analyzing intonation. In some approaches, pitch patterns are described as contours and analyzed in terms of levels of pitch as pitch phonemes and morphemes; in others, the patterns are described as tone units or tone groups, analyzed further as contrasts of nuclear tone, tonicity, etc. This is important to note that intonation performs several functions in a language - the most important function is as a signal of grammatical structure, where it performs a role similar to punctuation in writing. The marking of sentence, clause and other boundaries, and the contrast between some grammatical structures, such as questions and statements, may be made using intonation. For example, [illegible] by 'Are you asking me or telling me?' is regularly signaled by a cont[illegible] pitch, e.g., 'He's going, isn't he?' (= I'm asking you) opposed to 'He[illegible]'m

48 / 107

Topic-086: Intonation

Intonation refers (very) simply to the variations in the pitch of a speaker's voice (f_0) used to convey or alter meaning but in its broader and more popular sense intonation covers much of the same field as 'prosody' where variations in such things as voice quality, tempo and loudness are included. It is certainly possible to analyze pitch movement (or its acoustic counterpart, fundamental frequency) and find regular patterns that can be described and tabulated. Some experts look for an underlying basic pitch melody (or a small number of melodies) and then describe the factors that cause deviations from these

respectively. Glottalization as a process is used for any articulation involving a simultaneous glottal constriction (e.g., a glottal stop). In English, glottal stops are often used in this way to reinforce a voiceless plosive at the end of a word as in *what*. Such sounds, made while the glottis is closed, are produced without the direct involvement of air from the lungs. Air is compressed in the mouth or pharynx above the glottal closure, and released while the breath is still held thus the resultant sounds produced in this glottalic airstream mechanism are known as ejective sounds. They are also called 'glottalic' or glottalized sounds (though the latter term is often restricted to sounds where the glottal feature is a secondary articulation). In languages like Quechua and Hausa ejective consonants are used as phonemes. A further category of sounds involving a glottalic airstream mechanism is known as implosive.

Topic-093: Velaric Airstream Mechanism

are usually 4 of 6

number of positions thus modifying the form of speech sounds and changing the features of it. When brought into light this contact of vocal folds with each other, the shape of vibration (of air passage) is forced to produce phonation or voicing. So, based on the possibilities of the nature of vibration, the states of glottis are determined thus the vibration can be made to vary in many ways, resulting in differences in such things as pitch, loudness and voice quality. If a narrow opening is made between the vocal folds, friction noise can result and this is found in whispering and in the glottal fricative /h/. A more widely

open glottis is found in most voiceless consonants. In Table 6.6 (chapter six of your course book), four possible states of the glottis are given. Go through them and explore further.

Topic-098: Phonation Types

In order to further explain the nature of the phonation as a process, we need to know the possible phonation types and its description. There are mainly four possible glottis/larynx settings or types of phonation:

- Voiceless – when the folds are open apart and the air passing through the glottis freely (/t/ or /p/).
- Voiced – when the folds are tight together and there is vibration during the air passage though the glottis (e.g., /b/ or /d/).
- Creaky voice – when there is a slight opening in the front and the arytenoid cartilages are tight together, so that the vocal folds can vibrate only at the anterior end (the small opening at the top).
- Breathy or murmuring sound – when the vocal folds are apart but still they are vibrating - a breathy voice is like a whisper except voice.

Topic-099: Voicing and Consonants

Voi… important feature of spee…ds which is used not only as a feature but also as a distinction … describing sounds. There are soun… such as vowels, nasals and approximants i.e., sonor… which are usually voiced (though in pe…ar contexts the voicing may be weak or absent). On t…ther hand, there are sounds which m… voiced or voiceless such as fricatives and plosives (to…r called obstruents). Obstruents … most frequently found sounds that have both voicing and voi…ssness. Remember that … voiceless can make a phonemic distinction (in languages such as E… … a word can change if one uses a voiceless sound instead of a voiced sound. A glottal stop is only an allophonic variation and is used in RP before /p, t, k/. In some dialects these three can even be replaced by a glottal stop altogether. The symbol for a glottal stop is like a question mark [ʔ].

Lesson-17

ENGLISH WORDS AND SENTENCES-II

At the end of this section, the students will be able to:

- RECOGNIZE and EXPLAIN sentence rhythm, intonation and target tones.

Topic-085: Sentence Rhythm

Sentence rhythm is another feature of a connected speech. Actually, speech is perceived as a sequence of events in time, and the word rhythm is used to refer to the way events are distributed in time. Obvious example of vocal rhythms is chanting as part of games (for example, children calling words while skipping or cricket crowds calling their favorite team's name). In conversational speech, the

- Voiceless – when the folds are open apart and the air passing through the glottis freely (/t/ or /p/).
- Voiced – when the folds are tight together and there is vibration during the air passage though the glottis (e.g., /b/ or /d/).
- Creaky voice – when there is a slight opening in the front and the arytenoid cartilages are tight together, so that the vocal folds can vibrate only at the anterior end (the small opening at the top).
- Breathy or murmuring sound – when the vocal folds are apart but still they are vibrating - a breathy voice is like a whisper except voice

Topic-088: Target Tones

Although 'tone' as a word has a very wide range of meanings and uses in ordinary languages, its meaning in phonetics and phonology is quite restricted. It refers to an identifiable movement or level of pitch that is used in a linguistically contrastive way. In typical 'tone' languages, the linguistic function of tone is to change the meaning of a word. For example, in Mandarin (Chinese), / ma/ said with high pitch means 'mother' while / ma/ spoken on a low rising tone means 'hemp'. In other (non-tonal) languages, tone forms the central part of intonation, and the difference between, for example, a rising and a falling tone on a particular word may cause a different interpretation of the sentence in which it occurs. In the case of tone languages, it is usual to identify tones as being a property of individual syllables, whereas an intonational tone may be spread over many syllables. Similarly, in the analysis of English intonation, tone refers to one of the pitch possibilities for the tonic (or nuclear) syllable, a set usually including fall, rise,

1:27 80%
pitch that is used 1 of 2

Topic-087: Explaining Intonation

'Intonation' is pitch variation at sentence level and it could be described in terms of intonational phrase. In order to describe intonation, we need to analyze the role of a 'stressed syllable' (i.e., pitch change of one syllable) which further creates a major change 'tonic accent' (marked with an asterisk) to create the pitch peak in an intonational phrase. Similarly, a formal category of intonational phrase is also sometimes recognized (an utterance span dominated by boundary tones). As the part of suprasegmental phonology, intonation refers to the distinctive use of patterns of pitch, or melody. There are several ways for analyzing intonation. In some approaches, pitch patterns are described as contours and analyzed in terms of levels of pitch as pitch phonemes and morphemes; in others, the patterns are described as tone units or tone groups, analyzed further as contrasts of nuclear tone, tonicity, etc. This is important to note that intonation performs several functions in a language - the most important function is as a signal of grammatical structure, where it performs a role similar to punctuation in writing. The marking of sentence, clause and other boundaries, and the contrast between some grammatical structures, such as questions and statements, may be made using intonation. For example, the change in meaning illustrated by 'Are you asking me or telling me?' is regularly signaled by a contrast between 'rising' and 'falling' pitch, e.g., 'He's going, isn't he?' (= I'm asking you) opposed to 'He's going, isn't he!' (= I'm telling you). A second important role of intonation is in the communication of personal attitude (e.g., sarcasm, puzzlement, anger, etc.) which can all be signaled by contrasts in pitch along with other prosodic and paralinguistic features. Other roles of intonation in language have been suggested (e.g., as one of the ways of signaling social background).

Topic-088: Target Tones

Although 'tone' as a word has a very wide range of meanings and uses in ordinary languages, its meaning in phonetics and phonology is quite restricted. It refers to an identifiable movement or level of pitch that is used in a linguistically contrastive way. In typical 'tone' languages, the linguistic function of tone is to change the meaning of a word. For example, in Mandarin (Chinese), / ma/ said with high pitch means 'mother' while / ma/ spoken on a low rising tone means 'hemp'. In other (non-tonal) languages, tone forms the central part of intonation, and the difference between, for example, a rising and a falling tone on a particular word may cause a different interpretation of the sentence in which it occurs. In the case of tone languages, it is usual to identify tones as being a property of individual syllables, whereas an intonational tone may be spread over many syllables. Similarly, in the analysis of English intonation, tone refers to one of the pitch possibilities for the tonic (or nuclear) syllable, a set usually including fall, rise, fall–rise and rise–fall, though others are also suggested by various experts.

Topic-089: Explaining Target Tones

There are several ways for analyzing intonation. In some approaches, the pitch patterns are described as contours and are further analyzed in terms of levels of pitch as pitch phonemes and morphemes. In others, the patterns are described as tone units or tone groups, analyzed further as contrasts of nuclear tone, tonicity, etc. The three variables (1) pitch range, (2) height and (3) direction are generally distinguished. Some approaches (especially within pragmatics), operate with a much broader notion than that of the tone unit (i.e., intonational phrasing is a structured hierarchy of the intonational

constituents in conversation). A formal category of intonational phrase is also sometimes recognized (i.e., an utterance span dominated by boundary tones). One of the most recently developed methods is called the 'tone and break indices' (ToBI). This method is used for the description of intonation (H/L) representing pitch changes and showing pitch accent – phrase accent and boundary by showing tone and break indices. This is based on describing High (H) and Low (L) pitches in a sentence representing pitch changes and showing pitch accent – phrase accent and boundary (of the phrase).

Lesson-19

PHONATION

At the end of this section, the students will be able to:

- EXPLAIN various aspects of phonation and states of the glottis during the production of speech sounds.

Topic-095: Introduction to Phonation

The position of larynx (also known as sound box) and the vocal folds inside larynx are very important in the description of speech sounds. 'Phonation' is a technical term used for describing the forms of vibration of the vocal folds (or vocal cords) and the process is more commonly known as voicing. The glottis (which is defined as the space between the vocal folds) can assume a number of shapes (such as voiced, voiceless, murmuring and creaky positions). The most common positions of vocal folds are used to describe the two possible features of consonant sounds by considering sounds to be either voiceless with the vocal folds apart (such as /p/ and /t/) or voiced with the folds nearly together so that they will vibrate when air passes between them (such as /b/ and /g/). These glottal states are

Lesson-01

INTRODUCTION TO THE COURSE-I

At the end of this section, the students will be able to:

- KNOW about the overall sketch of the course including aims, objectives and the evaluation criteria for the course.

Topic-001: Introduction to the Course

Phonetics and Phonology (P&P), course code ENG507, is an introductory level module in phonetics and phonology. The course focuses on the linguistic study of speech sounds in a phonetic and phonological perspective. The phonetic component provides a detailed analysis and description of speech sounds with particular emphasis on articulatory phonetics. The phonology component examines the internal structure of simplex and complex word forms. The module is designed for beginners' level explaining the basic concepts of phonetics and phonology. In addition to reading and attending lectures, students are expected to do regular problem-solving exercises at the end of every chapter (given in the main textbook by Ladefoged and Johnson) intended to consolidate their

‘Intonation’ is pitch variation at sentence level and it could be described in terms of intonational phrase. In order to describe intonation, we need to analyze the role of a ‘stressed syllable’ (i.e., pitch change of one syllable) which further creates a major change ‘tonic accent’ (marked with an asterisk) to create the pitch peak in an intonational phrase. Similarly, a formal category of intonational phrase is also
