... common--too much food eaten during pregnancy may have little or detrimental effects, too much iron may be toxic, and too much bulk destroys a child's appetite. Specific nutrients along with psychosocial stimulation may be the best mix. This will be discussed in subsequent sections.

Childhood Malnutrition

Almost 30% of children fewer than 5 years of age in the world are underweight; most live in developing countries in **Africa** and South Asia. Typical malnourished children are not thin or wasted looking, but are short for their age or stunted. They are usually malnourished at moderate rather than severe levels. Even mild and moderate malnutrition lead to physical health, learning and social problems. Most mothers would be surprised if they were told that their child was malnourished because there is no obvious wasting or change in behavior if the child has been this way for months. However, when the child's weight and height are compared with other well-nourished children from the same region, the discrepancy is striking. For example, if well-nourished

THEORIES OF MOTIVATION

Victor Vroom's Expectancy Theory of Motivation

The Expectancy Theory of Victor Vroom deals with motivation and management. Vroom's theory assumes that behavior results from conscious choices among alternatives whose purpose it is to maximize pleasure and minimize pain. Together with Edward Lawler and Lyman Porter, Vroom suggested that the relationship between people's behavior at work and their goals was not as simple as was first imagined by other scientists. Vroom realized that an employee's performance is based on individual factors such as personality, skills, knowledge, experience and abilities.

- The expectancy theory says that individuals have different sets of goals and can be motivated to believe that:
- There is a positive correlation between efforts and performance,
- Favorable performance will result in a desirable reward,
- The reward will satisfy an important need,
- The desire to satisfy the need is strong enough to make the effort worthwhile.

Vroom's Expectancy Theory is based upon the following three beliefs:

Valence (Valence refers to the emotional orientations people hold with respect to outcomes [reward or depth of the want of an employee for extrinsic [money, promotion, time-off, benefits] or [satisfaction] rewards). Management must discover what employees value. **Expectancy** (Employee's different expectations and levels of confidence about what they are capable of doing). Management must discover what resources, training, or supervision employees need. **Instrumentality** (The perception of employees whether they will actually get what they desire even if it has been promised by a manager). Management must ensure that promises of rewards are fulfilled and that employees are aware of that. It suggests that an employee's beliefs about Expectancy, Instrumentality, and Valence interact psychologically to create a motivational force such that the employee acts in ways that bring pleasure and avoid pain. This can be 'calculated' via the following formula: $\text{Motivation} = \text{Valence} \times \text{Expectancy} \times \text{Instrumentality}$. This formula can be used to indicate and predict such things as job satisfaction, one's occupational choice, the likelihood of staying in a job, and the effort one might expend at work.

Porter-Lawler Model

the world in a variety of applications.

Introduction:

Personality Traits and the Five-Factor Model

Personality traits are defined as "dimensions of individual differences in tendencies to show consistent patterns of thoughts, feelings, and actions" (McCrae & Costa, 1990). They are familiar to laypersons, who use a huge vocabulary of trait descriptive adjectives (such as nervous, enthusiastic, original, accommodating, and careful) to describe themselves and others. Allport and Odbert (1936) identified some 4,000 trait names in the English language, and similar (although generally smaller) lists of traits have been compiled for many other languages, including Turkish and Chinese (Somer & Goldberg, 1999; Yang & Lee, 1971). It is apparent that trait concepts are important in every human language, and it would clearly be of great interest to compare traits across cultures. Are the same traits found everywhere? Are they organized in similar fashion? Do they show the same course of development and the same correlates? Or are traits products of culture that vary as dramatically as vocabularies and food preferences do?

These intriguing questions have been asked repeatedly by anthropologists and cross cultural psychologists, but until recently, research was severely hampered by the lack of an agreed-upon taxonomy of traits. It is obviously impossible to conduct cross-cultural studies of each of the 4,000 traits identified by Allport and Odbert, and without taxonomy, the selection of a subset of traits is likely to be arbitrary. Personality psychologists like Raymond Cattell and Hans Eysenck had long ago noted that traits could be organized into much smaller clusters of similar traits. For example, the terms *cautious*, *careful*, *deliberate*, *prudent*, and *thorough* are near-synonyms, and people who are careful are also likely to be described as cautious and thorough. In short, personality traits are structured, and a comprehensive yet parsimonious structure would greatly facilitate personality research.

(<http://www.who.int/infectious-disease-report>). If malnourished children survive the first five years, their quality of life will be impaired: they will be less able to learn at school, more fearful of unfamiliar people and new experiences, less persistent at solving daily problems, and less sociable. Simply increasing food intake is not a sufficient or even a wise solution: too much food eaten during pregnancy may have little or detrimental effects, too much iron may be toxic, and too much bulk destroys a child's appetite. Specific nutrients along with psychosocial stimulation may be the best mix. This will be discussed in subsequent sections.

Childhood Malnutrition

Almost 30% of children fewer than 5 years of age in the world are underweight; most live in developing countries in Africa and South Asia. Typical malnourished children are not thin or wasted looking, but are short for their age or stunted. They are usually malnourished at moderate rather than severe levels. Even mild and moderate malnutrition lead to physical health, learning and social problems. Most mothers would be surprised if they were told that their child was malnourished because there is no obvious wasting or change in behavior if the child has been this way for months. However, when the child's weight and height are compared with other well-nourished children from the same region, the discrepancy is striking. For example, if well-nourished

CULTURAL ASPECTS OF DEPRESSIVE EXPERIENCE AND DISORDERS

Lesson 7

Introduction:

The Importance of Cultural Considerations in Depressive Experience and Disorder

Within the last decade, depressive experience and disorder has emerged as one of the world's major health and social problems (e.g., Bebbington, 1993; Desjarlais, Eisenberg, Good, & Kleinman, 1995). This can be attributed to a spectrum of *biological* (e.g., longevity, chronic diseases, toxin exposure, malnutrition, medications), *psychological* (e.g., identity confusion and conflict, loss of meaning, learned helplessness, powerlessness) and *sociocultural and environmental* (e.g., role confusion and conflict, uprooting due to war and natural disasters, urbanization, rapid social change, cultural disintegration and collapse, and racism and sexism) factors associated with the *etiology*, exacerbation, and maintenance of depressive experience and disorder. As a result of the increased worldwide risk and burden of depressive experience and disorders (Murray & Lopez, 1996), it is essential researchers and professionals improve their understanding of the complex cultural knowledge, issues, and concerns related to this problem.

Cultural variations in the nature and meaning of depressive experience and disorder have critical implications for assessment, diagnosis/classification, and treatment because cultural variations imply cultural relativism regarding with regard to such critical variables as epistemology, personhood, self, body, health and disorder,

have health and productivity at home when they eat. They may be motivated by the sensory pleasures: the desire for energy, the feeling of being full, or the sociability of eating with others—or they may eat out of habit. However, the food preferences of adolescents are very similar to their parents, indicating family eating influences what we think and like about food. Moreover, there are commonly held beliefs about the good and bad effects of certain foods. Consequently, there are many personal, family, and cultural influences on the food we eat. But what is the cost of a poor diet and how easy is it to change a diet?

Cost of a Poor Diet

The cost of a poor diet is immense. While the interactive effect of malnutrition and infection is responsible for over half of child deaths in developing countries (Pelletier, Frongillo, Schroeder, & Habicht, 1995), it has been declared the number one health problem in the United States. Surprisingly, the overweight problem is starting to appear among urban women in developing countries such as India and Chile that are in transition to better economies. Obesity, whether experienced in Washington, Calcutta, Santiago or elsewhere, is bad for one's health because it can lead to heart disease, diabetes, and premature death. In poor countries, many women are short because of poor diets in youth and they are anemic because their diets lack iron; consequently many die while giving birth to a normal sized baby. However, the most pressing moral issue of our times is the wasted human potential in the millions of children who are malnourished either at birth or throughout their first five years. They are more likely than well-nourished children to become ill and die. More information on these infectious diseases can be found at the World Health Organization's website (<http://www.who.int/infectious-disease-report>). If malnourished children survive the first five years, their quality of life will be impaired: they will be less able to learn at school, more fearful of unfamiliar people and new experiences, less persistent at solving daily problems, and less sociable. Simply increasing food intake is not a sufficient or even a wise solution—too much food eaten during pregnancy may have little or no effect, too much iron may be toxic, and too much bulk destroys a child's appetite. Specific nutrients and their balance may be the best mix. This will be discussed in subsequent sections.

involved and interested in their surroundings, unhappier and more fearful. Work and learning therefore suffer along with mood. Consequently, anemic children show poorer language, motor, and eye-hand coordination abilities than non-anemic children (Grantham-McGregor & Ani, 2001). In developing countries, particularly in Africa and South Asia, 21.5 million children under 5 years of age, or 40% of preschoolers, are anemic. Iron deficiency is caused not only by an iron-deficient diet but also by malaria and hookworm infections. Hookworms, which are prevalent in feces-contaminated soil, enter through the sole of unshod feet and then sap blood through the intestine wall. They and other geohelminths prevent full use of food intake of school-age children who pick up worms in their travels around the community.

Iodine deficiency is thought to be the main cause of reduced brain capacity through its effect on the thymus and thyroid gland. It is simply bad fortune to live in a region where this element is not naturally found in the soil and so is lacking in plant food. Before iodine-fortified salt became available for purchase several years ago, 15% of school children 6 to 11 years of age in developing countries had an enlarged **goiter**, the main sign of iodine deficiency. Even today many families do not have access to iodized salt.

The most severe problems in psychological functioning are found in newborns of iodine deficient mothers because iodine is essential for early brain development.

Zinc has newly entered the list of essential nutrients for health, particularly in the early years when children are vulnerable to infections. Zinc supplements in the first year, given in syrup form, were found to reduce the duration and severity of acute and persistent diarrhea and pneumonia, especially in malnourished children. Perhaps because of the protection against infection, children on zinc supplements show better weight gains over the years.

Breast milk is universally acknowledged as the best nutrition for infants. Not only does it provide antibodies that protect the infant from early infections, but it contains all the nutrients listed above, such as fatty acids and protein, which infants may not get from commercially sold milks. Infants given breast milk alone for the first 4-6 months grow better, are healthier, and develop more mature mental abilities than children fed other commercial or cows' milks. Making sure that mothers offer their infants breast milk is a concern in all countries of the world.

Cultural Influences on Food Choices and Nutrition

It is not surprising that children and adolescents share food preferences with their parents rather than their friends. From birth, parents make most food choices for their children. Choices may be influenced by the foods that are available and the foods are appreciated or avoided by one's cultural group. However, because

Some Guidelines for Assessing and Treating Depressive Experience and Disorder in the Cross-Cultural Clinical Encounter

1. **Formal Training:** Clinicians should seek formal training in cross-cultural studies of psychology, psychopathology, and psychotherapy. These courses are now available at most universities and they should be required given the cultural pluralism of our society and the world.
2. **Cultural Fluency:** Clinicians should strive to develop language and cultural fluency and competence for those groups with whom much of their professional work occurs. If possible, this should include traveling to locations in which these groups live.
3. **Culturological Interview:** Clinicians should conduct a culturological interview (much as they conduct a psychiatric and a psychological interview) that can provide information regarding the patient's ethnocultural identity, cultural construction of reality, cultural explanatory models, culture-related stressors and coping methods.
4. **Cultural Participation:** Clinicians should work with the patient, family, and cultural consultants to develop a clinical assessment and treatment program that is valid for the patient. To be valid, this program must actively consider cultural variables much as clinicians now consider gender, age, gender preference, and other forms of social identity.
5. **Cultural Equivalency in Assessment:** Clinicians should be aware of the cultural limitations of clinical assessment methods for their patient because of non-equivalence in language, concepts, norms, and scaling.

quality of life will be impaired: they will be less able to learn at school, more fearful of unfamiliar people, new experiences, less persistent at solving daily problems, and less sociable. bananas, tubers such as potatoes, animal or vegetable oil, grains and rice. Fatty acids from oils are particularly important in forming the myelin sheath that surrounds nerves, allowing for a rapid response from the brain; researchers now realize that fatty acids are essential for maturation of the eye nerves and detection of light. Protein is found in certain foods such as meat, fish, eggs and legumes; only 15% of calories need be protein so this is not usually a problem. Recently we have come to realize that other nutrients required smaller amounts are also necessary for physical and mental health. These include vitamin A, iron, iodine, and zinc (World Health Organization, <http://www.who.int/nut>).

Vitamin A was only recently discovered to have **wide-ranging** effects in strengthening a child's resistance to illness such as diarrhea and measles, in addition to its well-known effect on vision. Children and adults who lack vitamin A first notice the effects when they walk outside at dusk--they can't see anything. Over time, the eye disease known as xerophthalmia blinds the person as the membrane over the eye becomes dry, wrinkled and eventually opaque. Three million children develop xerophthalmia each year; up to half a million become blind. Children who lack even small amounts of vitamin A have a weaker immune system and so they suffer longer and more severe bouts of diarrhea, measles, and pneumonia. Vitamin A deficiency is so widespread in countries in Africa and Asia, which up to 70% of children are considered at risk. Orange fruits and vegetables are the most common source of vitamin A.

- (2) Learning theories, including social learning theory;
- (3) Cognitive-developmental theory
- (4) Evolutionary psychology.

Aspects of morality: Asking what kind of "sense" the moral sense is leads directly to further questions, such as, is it knowledge of the rules, or feelings about right and wrong actions, or use of the rules to guide actual behavior? The fact that each of these questions appears to require an affirmative answer implies a complex structure for conscience, a structure comprising (at least) cognitive aspects such as knowledge and reasoning, moral **feelings**, and action or behavior. While all the major theories of morality try to address all these aspects to some extent, each of them takes a different aspect as seemingly the most basic. The psychoanalytic theory of the superego focuses to a large extent on the moral feelings of anxiety, shame, and guilt, generally ignoring cognitive and behavioral aspects (Freud, 1924a, 1924b). Social learning and behaviorist approaches place greatest emphasis on behavior, its consequences (direct or vicarious), and its stimulus conditions, to the relative exclusion of thinking and feeling (e.g., Bandura, 1977). Cognitive developmental theory is concerned mainly with moral reasoning, to the relative neglect of feeling and action (e.g., Piaget, 1932; Kohlberg, 1969). Evolutionary hypotheses, to the extent that they take into account subjective states of the person, focus on feelings as cues to action; however, this approach has so far concentrated on the selective value of prosocial action and the possible mechanisms by which both prosocial tendencies and social control tendencies may have been selected through evolution (e.g., Trivers, 1971). An important exception to the tendency to focus on a single aspect is the work of Hoffman (2000), whose

did not have enough reserves to cope with the next episode of diarrhea or respiratory infection. In addition to suffering poor health, underweight children suffer long-term problems in their ability to learn and solve problems, and in their emotional and social life.

The most immediate, but not the only, cause of malnutrition is the lack of calories that provide energy and protein for building body cells (Waterlow, 1992). Both are needed to put weight and height on a child. Calories are present in many foods, particularly those high in sugars, starches, and fats. These include fruits such as bananas, tubers such as potatoes, animal or vegetable oil, grains and rice. Fatty acids from oils are particularly important in forming the myelin sheath that surrounds nerves, allowing for a rapid response from the brain; researchers now realize that fatty acids are essential for maturation of the eye nerves and detection of light. Protein is found in certain foods such as meat, fish, eggs and legumes; only 15% of calories need be protein so this is not usually a problem. because they explicitly acknowledge clinician and patient realities, should be used more often in clinical settings. Qualitative methods, such as narrative assessment and therapy, should be used more often in clinical settings because of their biases and rely increasingly on diagnostic formulations that describe problem (i.e., symptom, disability) frequency and severity within identifiable settings and situations. In addition, the formulation should seek and formalize the differences between clinician, family, and patient constructions.

7. Cultural Collaboration and Options: Clinicians should evolve treatment intervention programs in collaboration with their clients. They should present explanations of their decisions and seek approval. Whenever possible, they should present therapeutic options including the use of alternative and complementary methods.

8. Cultural Experts: Clinicians should work with experts familiar with the cultural context of their patient's life style and disorder. These experts can provide services as referral agents, consultants, co-therapists, or therapists.

9. Cultural Awareness of History and Life Context: Clinicians should be fully aware of the history and life circumstances of their patients with regard to possible impacts of ethnic and racial minority status on the causes and expression of their disorders. This information can be part of the cultural interview. The critical consideration here is that the clinician comes to understand that the etiology and treatment of the problem may reside in factors external to the individual patient in such areas as poverty, injustice, inequity, cultural dislocation and abuse, marginalization, racism, and a host of other societal factors. Indeed, the clinician may need to work as both an individual and a social change agent.

Cultural Influences on Food Choices and Nutrition

It is not surprising that children and adolescents share food preferences with their parents rather than friends. From birth, parents make most food choices for their children. Choices may be influenced by the foods that are available and the foods are appreciated or avoided by one's cultural group. However, there is a great deal of variation within a culture as well as between cultures.

... mean levels of SWB, they also tend to base happiness on somewhat different experiences. In the past when SWB research was conducted primarily among North American participants, many researchers assumed that high self-esteem was the single most important ingredient of happiness. After all, what could be more important to happiness than having a positive self-view, that is, high self-esteem? Many Westerners might be surprised to learn, however, that the term self-esteem does not even exist in some cultures (for instance, in the Japanese, Chinese, or Korean language). We might wish to ask the question again: Is self-esteem equally critical for happiness across cultures? The answer is no, according to recent findings (Diener & Diener, 1995; Kwan, Bond, & Singelis, 1997). Self-esteem relates strongly with SWB in individualistic cultures, but the link becomes considerably weaker in collectivist cultures. Among female college students in India, for instance, Diener and Diener failed to find any significant association between self-esteem and SWB.

Another psychological condition traditionally viewed as very important for SWB is the possession of a consistent self-identity. All individuals think, feel, and behave somewhat differently in different social contexts (for example, when with a boyfriend versus when with a boss). Nevertheless, prominent Western psychologists have repeatedly asserted that, in order to achieve high levels of mental health, a person needs to maintain a consistent self-view across situations. This idea fits well with the dynamics of individualist cultures, where the inner self is believed to be the primary source of personal meaning and guidance. Because the self plays such a central role in everyday life, it becomes necessary to build and maintain a self-system that is well-organized and consistent. In collectivist cultures, however, the utmost concern of everyday life is maintaining a smooth, harmonious relationship with other people. In order to achieve this goal of interpersonal harmony, the self needs to be highly sensitive to social cues, and in many cases, adjust the self according to the needs and expectations of other people. In other words, the self is required to be quite flexible across social situations in cultures where values promoting harmony (e.g., modesty, obedience) often overshadow the importance of consistency.

... recently examined the consistency of Korean and American students' self-views in relation to their SWB.

... they are shaped, experienced, communicated, and responded to by others. That is to say, they are decontextualized. This is a serious problem because decontextualization permits the researcher/clinician to assign their ethnocentric meanings and interpretations to the problems independent of the context in which they emerge and are sustained. There may be little consideration for situation stressors as well as normative personality configurations that may differ from those of the researcher/clinician.

The Concept of Depressive Experience and Disorder

1. Western Historical Perspectives

Depressive experience and disorder have long been a source of concern in Western cultural traditions. "Depression," according to Jackson (1986), is derived from the Latin word "deprimere" meaning "to press down." With the passage of time, "depression" gained increasing currency in English, French, and German medical treatises. Initially, it was used as a subset of "melancholy," then as a synonym, and later as a replacement for the term. Hippocrates (330-399 BCE) included melancholia within his tripartite classification of disorders (i.e., mania, melancholia, phrenitis). He considered its cause to be a function of excessive black bile. Stanley Jackson (1986), in his scholarly book on the topic, *Melancholy and Depression: From Hippocratic Times to the Present*, points out that the term "melancholy" was first used in ancient Greece to describe a disorder characterized by fear, nervous conduct, and sorrow. By the fourth century AD, the Christian Church had begun to shape the concept of melancholy with its use of the term *acedia* to designate a cluster of feelings and behaviors associated with "dejection" (Jackson, 1986). The condition was often associated with religious fervor among monks and others that practiced isolation and self-denial. It came to mean sluggishness, lassitude, torpor, and non-caring, as well as those emotions associated with *tristitia* (i.e., sadness) and *desperatio* (i.e., despair) (see Jackson, 1986, pp. 65-70).

"Melancholy" was used extensively in Europe until the 17th century when the term "depression" began to acquire currency. The promotion of "melancholy" as a major mood disorder, dysfunction, and problematic

malnourished children survive the first five years, their new experiences, less persistent at solving daily problems, and less sociable. Simply increasing food intake is not a sufficient or even a wise solution—too much food eaten during pregnancy may have little or detrimental effects, too much iron may be toxic, and too much bulk destroys a child's appetite. Specific nutrients along with psychosocial stimulation may be the best mix. This will be discussed in subsequent sections.

Childhood Malnutrition

Almost 30% of children fewer than 5 years of age in the world are underweight; most live in developing countries in Africa and South Asia. Typical malnourished children are not thin or wasted looking, but are short for their age or stunted. They are usually malnourished at moderate rather than severe levels. Even mild and moderate malnutrition lead to physical health, learning and social problems. Most mothers would be surprised if they were told that their child was malnourished because there is no obvious wasting or change in behavior if the child has been this way for months. However, when the child's weight and height are compared with other well-nourished children from the same region, the discrepancy is striking. For example; if well-nourished

Cross Cultural psychology (PSY - 515)

characterological orientation was assisted by the publication of Robert Burton's tome, *The Anatomy of Melancholia*, published in 1652.

This book gained immediate and widespread popularity and remained a vital source of clinical insight and acumen on mood problems for subsequent centuries because of its encyclopedic coverage of the topic. It is noteworthy, that "melancholy" has re-emerged in DSM IV as a major sub-type of depression characterized by symptoms associated with the previous concept of "endogenous depression" (e.g., APA, 1994; Jackson, 1986). The continuous presence of the terms "melancholy" and "depression" through the past centuries of Western European and North American history indeed its literal dominance of psychiatric thought and practice suggests a massive and widespread cultural pre-occupation with the topic. This is especially true because of Judao-Christian religious concerns with guilt, sin, sloth, despair, and worthlessness. But, the longevity and pervasiveness of this pre-occupation has not necessarily increased our understanding of the topic, especially with regard to its etiology, assessment, and treatment. Theories and classification systems abound today, as do a multiplicity of approaches to measurement and diagnosis/classification (e.g., APA, 1994), but controversy and debate continue as professionals and researchers seek to disentangle the complex web of biological, psychological, and social determinants, and the historical overlays that have shaped our understanding.

Problems in Psychiatric Diagnosis and Classification

Within Western psychiatry, biological and psychological perspectives have dominated thinking, and little attention has been directed to ethnocultural variations in depressive experience and disorder, and the

more to the story. In this chapter, some of the latest findings from the culture and subjective well-being are introduced. Additional sources on this topic can be found in Suh (1999, 2000) and Diener, Oishi, and Lucas (in press).

Subjective Well-Being

In order to conduct scientific research, first, it is imperative to have a working definition. One of the most commonly used term in the field of psychology is subjective well-being (SWB; for review, see Diener, 1999). Subjective well-being includes three components:

- 1) Life satisfaction-a cognitive evaluation of one's overall life,
- 2) The presence of positive emotional experiences,
- 3) The absence of negative emotional experiences.

personality configurations that may differ from those of the researcher/clinician.

The Concept of Depressive Experience and Disorder

1. Western Historical Perspectives

Depressive experience and disorder have long been a source of concern in Western cultural traditions. "Depression," according to Jackson (1986), is derived from the Latin word "deprimere" meaning "to press down." With the passage of time, "depression" gained increasing currency in English, French, and German medical treatises. Initially, it was used as a subset of "melancholy," then as a synonym, and later as a replacement for the term. Hippocrates (330-399 BCE) included melancholia within his tripartite classification of disorders (i.e., mania, melancholia, phrenitis). He considered its cause to be a function of excessive black bile. Stanley Jackson (1986), in his scholarly book on the topic, *Melancholy and Depression: From Hippocratic Times to the Present*, points out that the term "melancholy" was first used in ancient Greece to describe a disorder characterized by fear, nervous conduct, and sorrow. By the fourth century AD, the Christian Church had begun to shape the concept of melancholy with its use of the term *acedia* to designate a cluster of feelings and behaviors associated with "dejection" (Jackson, 1986). The condition was often associated with religious fervor among monks and others that practiced isolation and self-denial. It came to mean sluggishness, lassitude, torpor, and non-caring, as well as those emotions associated with *tristitia* (i.e., sadness) and *desperatio* (i.e., despair) (see Jackson, 1986, pp. 65-70).

Raymond Cattell and Hans Eysenck had long ago noted that traits could be organized into much smaller clusters of similar traits. For example, the terms careful, cautious, deliberate, and thorough are near-synonyms, and people who are careful are also likely to be described as cautious and thorough. In short, personality traits are structured, and a comprehensive yet parsimonious structure would greatly facilitate personality research. Disputes about which structure was best continued for decades, but toward the end of the last century it became clear to most personality psychologists that most traits could be described in terms of **five factors** or dimensions. The organization of many specific traits in terms of the five factors of Neuroticism (N), Extraversion (E), Openness to Experience (O), Agreeableness (A), and Conscientiousness (C) is known as the Five-Factor Model (FFM; McCrae & John, 1992). Individuals who are high in N are likely to be anxious, easily depressed, and irritable, whereas those who are low in N are calm, even-tempered, and emotionally stable. Extraverts are lively, cheerful, and sociable; introverts are sober and taciturn. Open men and women are curious, original, and artistic; closed people are conventional and down-to-earth. Agreeableness is characterized by trust, compassion and modesty; Conscientiousness is seen in organization, punctuality, and purposefulness. Originally, the FFM was discovered through analyses of English-language trait names (Tupes & Christal, 1961/1992), and it is possible to measure an individual's standing on each of the five factors by asking them to rate themselves on a series of adjectives (Goldberg, 1992). But it is also possible to measure traits through the use of personality questionnaires, in which respondents indicate the extent to which they are accurately described by a series of statements about characteristic thoughts, feelings, and behaviors. A wide variety of measures of the FFM have now been developed (De Raad & Perugini, in press), of which the most widely used is the Revised NEO Personality Inventory (NEO-PI-R; Costa & McCrae, 1992). The NEO-PI-R assesses 30 specific traits, six for each of the five factors, and has been shown to be a reliable and valid measure for the

...negative emotions (such as anxiety, person's subjective perception about her own well-being is of paramount importance, which is shaped in complex ways by cultural factors.

Some Cultures are Happier than Others

There are substantial differences in the mean levels of SWB reported by different cultural members. A cross cultural research is conducted and the data come from a sample that consisted of more than six thousand college students from 43 nations. The mean life satisfaction ratings, on a 7-point scale, ranged from 3.3 (China) to 5.4 (Netherlands) in this sample. Nations not only differ in how much SWB they actually experience, but they also have different opinions on the ideal levels of SWB (the right columns under "Norm"). **Brazilians** (6.2 on a 7-point scale), for example, think it is very desirable to experience positive emotions, whereas the Chinese (4.5) show comparably less enthusiasm for the idea of feeling positive emotions. One notable finding is that, across nations, the norms for positive affect correlate significantly with the level of positive affect experienced in everyday life. For instance, students in nations that report high mean levels of positive affect (high PA experience) also tend to think it is very desirable to experience positive emotions (high PA norm). Such a relation between actual experience and norm does not exist for negative affect, although the exact reasons are unclear at present.

Why do cultural differences in SWB occur? Traditionally, many scholars have pointed out the fact that happier nations are simply wealthier. No doubt, there is a strong association between income (e.g., GNP) and SWB

Medical Definition of DSM - RxL

children of 4 years of age weigh on average 16 kg or 35.2 pounds, a child of 12.5 kg or 27.5 pounds will be considered underweight and therefore malnourished. This is based on a rough definition of moderate malnutrition as less than 80% of the expected weight, though the World Health Organization now uses a more accurate formula based on standard deviations from the average. Likewise, if well-nourished children of 4 years of age measures 102 cm or 40 inches in height, a child of 90 cm or 35 inches will be considered moderately stunted, using a rough calculation of less than 90% of expected height. Adults can calculate their own body mass index (BMI) as the quotient of weight (kg) / height² (m²). Somewhere between 19 and 23 is considered healthy; over 25 is overweight, 30 obese, and 17 underweight. The new standards published in 2000 by the Centers for Disease Control are available (<http://www.cdc.gov/growthcharts>). Close to 170 million children are malnourished if we use weight as our indicator of malnutrition. Across all developing countries, 28% of children fewer than 5 years of age are malnourished. For example, according to UNICEF (2001) who collects and publishes this information, the figures are 56% in Bangladesh, 53% in India, 47% in Ethiopia, 34% in Indonesia, 31% in Nigeria, 28% in the Philippines, and 5% in Costa Rica. Most of them were not born with low birth weight -- approximately 16% of newborns in developing countries are low birth weight (less than 2500 gm) even though they are full term (37-40 weeks). If breastfed, as most rural children are, they probably thrived in the first 6 months on breast milk alone. However, most of these children probably did not gain enough weight after that point both because of infections such as diarrhea and pneumonia and because the food offered was of insufficient quantity and quality for growth and illness recovery. As a result their weight and height did not rise as it should and their

formalize the differences between clinician, family, and patient constructions.

7. Cultural Collaboration and Options: Clinicians should evolve treatment intervention programs in collaboration with their clients. They should present explanations of their decisions and seek approval. Whenever possible, they should present therapeutic options including the use of alternative and complementary methods.

8. Cultural Experts: Clinicians should work with experts familiar with the cultural context of their patient's life style and disorder. These experts can provide services as referral agents, consultants, co-therapists, or therapists.

9. Cultural Awareness of History and Life Context: Clinicians should be fully aware of the history and life circumstances of their patients with regard to possible impacts of ethnic and racial minority status on the causes and expression of their disorders. This information can be part of the culturological interview. The critical consideration here is that the clinician comes to understand that the etiology and treatment of the problem may reside in factors external to the individual patient in such areas as poverty, injustice, inequity, cultural dislocation and abuse, marginalization, racism, and a host of other societal factors. Indeed, the clinician may need to work as both an individual and a social change agent.

...in many foods, particularly those high in sugars, starches, and fats. These include fruits such as bananas, tubers such as potatoes, animal or vegetable oil, grains and rice. Fatty acids from oils are particularly important in forming the myelin sheath that surrounds nerves, allowing for a rapid response from the brain; researchers now realize that fatty acids are essential for maturation of the eye nerves and detection of light. Protein is found in certain foods such as meat, fish, eggs and legumes; only 15% of calories need be protein so this is not usually a problem. Recently we have come to realize that other nutrients required smaller amounts are also necessary for physical and mental health. These include vitamin A, iron, iodine, and zinc (World Health Organization, <http://www.who.int/nut>).

Vitamin A was only recently discovered to have wide-ranging effects in strengthening a child's resistance to illness such as diarrhea and measles, in addition to its well-known effect on vision. Children and adults who lack vitamin A first notice the effects when they walk outside at dusk—they can't see anything. Over time, the eye disease known as xerophthalmia blinds the person as the membrane over the eye becomes dry, wrinkled and eventually opaque. Three million children develop xerophthalmia each year; up to half a million become blind. Children who lack even small amounts of vitamin A have a weaker immune system and so they suffer longer and more severe bouts of diarrhea, measles, and pneumonia. Vitamin A deficiency is so widespread in countries in Africa and Asia, which up to 70% of children are considered at risk. Orange fruits and vegetables are the most common source of vitamin A.

Vitamin A deficiency is so widespread in 70% of children are considered at risk. Orange fruits and vegetables are

and thyroid gland. It is simply bad fortune to live in a region where this element is not naturally found in the soil and so is lacking in plant food. Before iodine-fortified salt became available for purchase several years ago, 15% of school children 6 to 11 years of age in developing countries had an enlarged goiter, the main sign of iodine deficiency. Even today many families do not have access to iodized salt.

The most severe problems in psychological functioning are found in newborns of iodine deficient mothers because iodine is essential for early brain development.

Zinc has newly entered the list of essential nutrients for health, particularly in the early years when children are vulnerable to infections. Zinc supplements in the first year, given in syrup form, were found to reduce the duration and severity of acute and persistent diarrhea and pneumonia, especially in malnourished children. Perhaps because of the protection against infection, children on zinc supplements show better weight gains over the years.

Breast milk is universally acknowledged as the best nutrition for infants. Not only does it provide antibodies that protect the infant from early infections, but it contains all the nutrients listed above, such as fatty acids and protein, which infants may not get from commercially, sold milks. Infants given breast milk alone for the first 4-6 months **grow better**, are healthier, and develop more mature mental abilities than children fed other commercial or cows' milks. Making sure that mothers offer their infants breast milk is a concern in all countries of the world.

Cultural Influences on Food Choices and Nutrition

It is not surprising that children and adolescents share food preferences with their parents rather than their friends. From birth, parents make most food choices for their children. Choices may be influenced by the foods that are available and the foods are appreciated or avoided by one's cultural group. However, because

in Agreeableness and Conscientiousness from adolescence to adulthood—also appear to be universal, as are systematic patterns, but their interpretation is uncertain. The FFM is currently in use by psychologists around the world in a variety of applications.

Introduction:

Personality Traits and the Five-Factor Model

Personality traits are defined as "dimensions of individual differences in tendencies to show consistent patterns of thoughts, feelings, and actions" (McCrae & Costa, 1990). They are familiar to laypersons, who use a huge vocabulary of trait descriptive adjectives (such as nervous, enthusiastic, original, accommodating, and careful) to describe themselves and others. Allport and Odbert (1936) identified some 4,000 trait names in the English language, and similar (although generally smaller) lists of traits have been compiled for many other languages, including Turkish and Chinese (Somer & Goldberg, 1999; Yang & Lee, 1971). It is apparent that trait concepts are important in every human language, and it would clearly be of great interest to compare traits across cultures. Are the same traits found everywhere? Are they organized in similar fashion? Do they show the same course of development and the same correlates? Or are traits products of culture that vary as dramatically as vocabularies and food preferences do?

These intriguing questions have been asked repeatedly by anthropologists and cross cultural psychologists, but until recently, research was severely hampered by the lack of an agreed-upon taxonomy of traits. It is obviously impossible to conduct cross-cultural studies of each of the 4,000 traits identified by Allport and Odbert, and without taxonomy, the selection of a subset of traits is likely to be arbitrary. Personality psychologists like Raymond Cattell and Hans Eysenck had long ago noted that traits could be organized into much smaller clusters of similar traits. For example, the terms careful, cautious, deliberate, and thorough are near-synonyms, and people who are careful are also likely to be described as cautious and thorough. In short, personality traits
