Category VI	Category III is not aimed at sustainable resource use.

LECTURE 70-71: Category IV: Habitat-Species Management Area

Habitat-Species Management Area

Definition: IUCN Management Category IV (Habitat/Species Management Area) refers to areas that are managed to protect particular species or habitats. They are defined by IUCN as *"protected areas aiming to protect particular species or habitats and management reflect this priority.*

Primary objective: To maintain, conserve and restore species and habitats.

Other objectives

- To protect vegetation patterns.
- To protect fragments of habitats as components of landscape or seascape-scale conservation strategies.
- To develop public education and appreciation of the species or habitat
- Developed by the International Union for Conservation of Nature (IUCN) with support of the World Commission on Protected Areas (WCPA) and other international institutions such as the Convention on Biological Diversity (CBD), and assigned by national governments.

Distinguishing features

- Protection of particular species
- Protection of habitats
- Active management to maintain target species
- Active management of culturally-defined ecosystems

Muhammad Kashif 03064963933

Role in the landscape/seascape

- Protect critically endangered populations of species.
- Protect rare or threatened habitats.
- Provide flexible management strategies and options in buffer zones around, or connectivity conservation corridors between, more strictly protected areas that are more acceptable to local communities and other stakeholders;
- Maintain species that have become dependent on cultural landscapes where their original habitats have disappeared or been altered.

Management

These areas are managed to maintain or restore certain species and/or habitats, and this can be carried out by a range of actors depending on the governance type of the area (see IUCN Protected Area Management Categories for information on governance types). These are often areas that have already undergone substantial modification, where a high degree of human pressure often exists, and significant management intervention is necessary. Category IV areas will generally be publically accessible.

Legal and compliance

The classification of a category IV protected area requires that such areas are managed for conservation by legal or other effective means, and therefore legal recognition and protection at the national or subnational level is likely to be present in these sites. The level of legal protection will however vary between countries, and will depend on the governance type of the area, as they receive differing levels of recognition by government in different countries. Nonetheless a number of national laws are likely to apply to these sites that deter large-scale economic activities in order to maintain the conservation values of these areas.

Biodiversity importance

Category IV areas are important for their role in 'plugging the gaps' in conservation strategies by protecting key species or habitats in ecosystems. It provides a management approach for areas th have already undergone substantial modification, necessitating protection of remaining fragmer identified target species with or without intervention.

Socio-cultural values

- While Category IV areas are not necessarily associated with human presence and interven many exist in crowded landscapes and seascapes where human pressure is comparatively greater, both in terms of potential illegal use and visitor pressure
- Many category IV protected areas exist in crowded landscapes and seascapes.
- The category IV protected areas that rely on regular management intervention need appropriate resources from the management authority.
- Because they usually protect part of an ecosystem, successful long-term management of category IV protected areas necessitates careful monitoring and an even greater-than-usual emphasis on overall ecosystem approaches and compatible management in other parts of the

Select text

The preserved material is washed few times to remove the cryoprotectant. This material is then recultured in a fresh medium

7. Measurement of viability

- There is possibility of death of cells due to storage stress.
- Thus viability can be found at any stage.
- It is calculated by formula :

$$\left(\frac{No\ of\ cells\ growing}{No\ of\ cells\ thawed}\right) \times 100$$

8.Plant regeneration

The viable seeds are cultured on non specific growth medium. Suitable environmental conditions are maintained.

Cory-conservation of animal genetic resources

Cory-conservation of animal genetic resources is a strategy wherein samples of animal genetic materials are preserved cryogenically.

- Animal genetic resources, as defined by the Food and Agriculture Organization of the United Nations, are "those animal species that are used, or may be used, for the production of food and agriculture, and the populations within each of them
- Genetic materials that are usually cryogenically preserved include sperm, oocytes, embryos and somatic cells.
- Cryogenic facilities are called gene banks and can vary greatly in size usually according to the economic resources available.
- They must be able to facilitate germplasm collection, processing, freezing, and long term storage, all in a hygienic and organized manner.
- Cryo-conservation is the process of freezing cells and tissues using liquid nitrogen to achieve extreme low temperatures with the intent of using the preserved sample to prevent the loss of genetic diversity.
- Semen, embryos, oocytes, somatic cells, nuclear DNA, and other types of biomaterial such as blood and serum can be stored using cryopreservation, in order to preserve genetic materials.

Muhammad Kashif 03064963933

Methodology:

1. **Collection:** Here are several ways to collect the genetic materials based on which type of germplasm. **Examples:** Embryo, Somatic cells

2. **Freezing:** There are two cryopreservation freezing methods

- Slow freezing
- Vitrification

LECTURE 63: Advantages and disadvantages of Cryopreservation

Advantages:

- Cryopreservation helps in the preservation of biological materials.
- Cryopreservation is used to maintain the biosynthetic properties of plants
- Sperm, gametes, embryos, tissues, bone marrow, organ can be preserved.
- Helps to study the adapting nature of plants and animals under the low temperature.
- Used to preserve the genetic materials of the plants which are on the verge of extinction
- Prevent in breeding
- Reduced risk of microbial contamination
- Reduced risk of cross contamination with other cell lines
- Reduced risk of genetic drift and morphological changes
- Embryo cryopreservation is used most often to store good quality excess em from an IVF treatment cycle.
- Embryos can be stored for a patient who elects to have her eggs fertilized with d Pregnancies have been reported from embryos stored for 16 years.
- Human sperm cryopreservation is widely used to store donor and partner spermatozoa to preserve sperms
- It also ensure the recovery of a small number of spermatozoa in several male factor infertility17 .
- It is commonly called sperm-banking is a procedure to preserve sperm cells.

Disadvantages:

11:15 Select text

boys who need to have gonado toxic therapy

Embryo cryopreservation

Embryo cryopreservation is used most often to store goodquality excess embryos resulting from an IVF treatment cycle. Embryos can be stored for a patient who elects to have her eggs fertilized with donar sperms. Pregnancies have been reported from embryos stored for 16 years

Cryopreservation of ovarian tissue

Ovarian tissue cryopreservation is considered to be an experimental technique for fertility preservation. This procedure is an option for patients who require immediate gonadotoxic treatment of aggressive malignancies when there is insufficient time to allow the woman to undergo ovulation induction, oocyte retrieval and crypreservation oocytes and/or embryos.

Cryopreservation of sperm:

Today human sperm cryopreservation is widely used to store donor and partner spermatozoa before assisted reproduction treatments to preserve spermatozoa before therapy for malignant diseases, vasectomy or surgical in fertility treatments and to ensure the recovery of a small number of spermatozoa in several male factor infertility

Cryopreservation of stem cell:

An important application of cryopreservation is in the freezing and storage of hematopoietic stem cell, which are found in the bone marrow rescue, hematopoietic stem cells are collected from a patient's bone marrow prior to treatment with high-dose chemotherapy. Following treatment, the patient's cryopreserved cells are thawed and infuse back into the body. This procedure is necessary, since high dose chemotherapy is extremely toxic to the bone marrow

Preservation of micro-biology cultures:

Bacteria and fungi can be kept short term refrigerated however, cell division and metabolism is not completely arrested and thus is not an optimal option for long term storage or to preserve cultures genetically or phenotypically as cell divisions can led to mutations

To conserve plant biodiversity

conservation of plant biodiversity is an important issue concerning the human population worldwide. Conservation of plant biodiversity can be performed in situ and ex situ. These two methods are complementary and are not exclusive. They offer different alternatives for conservation, but selection of the appropriate strategy should be based on a number of criteria, including the biological nature of the species and the feasibility of applying the chosen methods 22 . At present biotechnological methods have been used to conserve endangered, rare crop ornamental, medicinal and forest species for short-,medium-, and long- term

Muhammad Kashif 03064963933

Future of cryopreservation

Vitrification method of cryopreservation may bring new opportunities to research protocols. It is still an experimental procedure. There are two major concern about vitrification - toxicity of high concentration of cryoprotectants used and microbial contamination of liquid nitrogen. Several IVF programs have adopted the vitrification method as the sole procedure for day-3 human embryos and for human blastocysts, with excellent survival and pregnancy rates. The challenge now is to find a protocol to successfully vitrify human oocytes for which the slow freezing method has yet to produce acceptable.

LECTURE -65: Protected areas

What are Protected areas?

"A clearly defined geographical space, recognized, dedicated and managed, th
legal or other effective means, to achieve the long-term conservation of nature
associated ecosystem services and cultural values"

History of protected areas

The earliest types of protected areas for the conservation of resources can be traced back to around 200 BC when land owned by royalty was designated as private hunting reserves. Gradually, protected areas were opened or created for public recreational use. One of the earliest modern protected areas is considered to be Yellowstone National Park, designated in 1872 as a 'public park or pleasuring ground for the benefit and enjoyment of the people'

In 1962, the First Conference on National Parks was held and the first UN List of National Parks and
