BIO 503 GDB solution Spring 2021

Physics Approach to study Macromolecules at Nanoscale.

Physics provides knowledge about the many macromolecules which deals them at a nanoscale. Physics is the broadest definitions these terms refer to the science and technology that derives from being able to assemble, manipulate, observe and control matter on length scales from one nanometre up to 100 nanometres for instance the size of a protein molecule is 5 nm. Nanoscience provides important opportunities for theory and computation to lead in the discovery process because the experimental tools often provide an incomplete picture of the structure and function of nanomaterial. This theory can often fill in missing features crucial to understanding what is being measured. Physics approach to nanoscale can play such a useful role for micrometer-scale systems, are sometimes incapable of describing nanoscale properties due to incomplete incorporation of the underlying physics in the size-dependent materials parameters. Nano biophysics that are having an undeniable impact in real life. For example, next generation sequencing which resides in our understanding of the physics of the pairing and replication of DNA strands.
