Capillaries connect the **arteries** to **veins**. The **arteries** deliver the oxygen-rich blood to the **capillaries**, where the actual exchange of oxygen and carbon dioxide occurs. The **capillaries** then deliver the waste-rich blood to the **veins** for transport back to the lungs and heart. **Veins** carry the blood back to the heart.

arteries veins and capillaries

What is difference between arteries veins and capillaries?

Zainab Official

Arteries transport blood away from the heart. **Veins** return blood back toward the heart. **Capillaries** surround body cells and tissues to deliver and absorb oxygen, nutrients, and other substances.

What are the 3 types of veins?

What are the 3 types of blood vessels and their functions?

Zainab Official

There are three main types of blood vessels:

- Arteries. They carry oxygen-rich blood away from the heart to all of the **body's** tissues. ...
- Capillaries. These small blood vessels connect the arteries and the veins. ...
- Veins. These are blood vessels that take blood back to the heart.

define hemoglobin

haemoglobin

/ˌhiːməˈgləʊbɪn/

noun BIOCHEMISTRY

noun: **hemoglobin**

a red protein responsible for transporting oxygen in the blood of vertebrates. Its molecule comprises four subunits, each containing an iron atom bound to a haem group.

Definitions from Oxford Languages *Feedback*

Zainab Official

Translations and more definitions

Hemoglobin

Protein

Hemoglobin, or haemoglobin + -o- + globulin, abbreviated Hb or Hgb, is the iron-containing oxygen-transport metalloprotein in the red blood cells of almost all vertebrates as well as the tissues of some invertebrates. Hemoglobin in blood carries oxygen from the lungs or gills to the rest of the body.

Wikipedia

Scanned with CamScanner

What is hemoglobin and its function?

About 70 percent of your body's iron is found in the red blood cells of your blood called **hemoglobin** and in muscle cells called myoglobin. **Hemoglobin** is essential for transferring oxygen in your blood from the lungs to the tissues. Myoglobin, in muscle cells, accepts, stores, transports and releases oxygen.

what is the fixed a membrane n

People also ask

What is fixed membrane receptor mechanism?

Zainab Official

The **fixed** – **membrane** – **receptor mechanism**, applies to hormones that are proteins or amines. Because they are water – soluble and cannot diffuse across the plasma **membrane**, these hormones _initiate their response by means of specialized **receptors** on the plasma **membrane** of the target cell.

Vaccine Types

There are several different types of vaccines. Each type is designed to teach your immune system how to fight off certain kinds of germs —and the serious diseases they cause.

When scientists create vaccines, they consider:

- How your immune system responds to the germ
- Who needs to be vaccinated against the germ
- The best technology or approach to create the vaccine

Zainab Official

Based on a number of these factors, scientists decide which type of vaccine they will make. There are several types of vaccines, including:

- Inactivated vaccines
- Live-attenuated vaccines
- Messenger RNA (mRNA) vaccines
- Subunit, recombinant, polysaccharide, and conjugate vaccines
- Toxoid vaccines
- Viral vector vaccines

Scanned with CamScanner

Inactivated vaccines

Inactivated vaccines use the killed version of the germ that causes a disease.

Inactivated vaccines usually don't provide immunity (protection) that's as strong as live vaccines. So you may need several doses over time (booster shots) in order to get ongoing immunity against diseases.

Inactivated vaccines are used to protect against:

- Hepatitis A
- Flu (shot only)
- Polio (shot only)
- Rabies

Zainab Official

Live-attenuated vaccines

Live vaccines use a weakened (or attenuated) form of the germ that causes a disease.

Because these vaccines are so similar to the natural infection that they help prevent, they create a strong and long-lasting immune response. Just 1 or 2 doses of most live vaccines can give you a lifetime of protection against a germ and the disease it causes.

Scanned with CamScanner

Messenger RNA vaccines —also called mRNA vaccines

Researchers have been studying and working with mRNA vaccines for decades and this technology was used to make some of the COVID-19 vaccines. mRNA vaccines make proteins in order to trigger an immune response. mRNA vaccines have several benefits compared to other types of vaccines, including shorter manufacturing times and, because they do not contain a live virus, no risk of causing disease in the person getting vaccinated.

Zainab Official

mRNA vaccines are used to protect against:

- COVID-19

Subunit, recombinant, polysaccharide, and conjugate vaccines

Subunit, recombinant, polysaccharide, and conjugate vaccines use specific pieces of the germ—like its protein, sugar, or capsid (a casing around the germ).

Scanned with CamScanner

Toxoid vaccines

Toxoid vaccines use a toxin (harmful product) made by the germ that causes a disease. They create immunity to the parts of the germ that cause a disease instead of the germ itself. That means the immune response is targeted to the toxin instead of the whole germ.

Like some other types of vaccines, you may need booster shots to get ongoing protection against diseases.

Toxoid vaccines are used to protect against:

- Diphtheria
- Tetanus

Zainab Official

Viral vector vaccines

For decades, scientists studied viral vector vaccines. Some vaccines recently used for Ebola outbreaks have used viral vector technology, and a number of studies have focused on viral vector vaccines against other infectious diseases such as Zika, flu, and HIV. Scientists used this technology to make COVID-19 vaccines as well.

what is home hemocyanin

oxygen molecule (O_2).

People also ask

What is hemocyanin for?

Zainab Official

Hemocyanins are respiratory proteins that use copper binding sites to bind and transport oxygen in a variety of arthropods and mollusks. **Hemocyanins**, like hemoglobin, are multi-subunit molecules where each subunit (arthropods) or functional unit of a subunit (mollusks) binds oxygen.
