Solution:

Sequence alignments are useful in bioinformatics for identifying sequence similarity, producing phylogenetic trees, and developing homology models of protein structures. Multiple sequence alignment (MSA) is a common tool in phylogenetic analysis, where the evolutionary tree of different organisms are identified and organized in a hierarchical structure in which closely related species are physically placed near each other. MSAs are often used to create a phylogenetic tree, tree of life, due to the two distinct feature that are most functional domains are known and well annotated in sequences and the capability to find conserved regions that are known to be functionally important.
